

Fiscal Convergence in the European Union

Evžen Kočenda^a, Ali M. Kutan^b, and Taner M. Yigit^c

Abstract

We empirically examine the fiscal convergence of the recent ten European Union (EU) members using the Maastricht fiscal convergence criteria. We test for absolute beta and sigma convergence of the new members in comparison to the Maastricht benchmarks as well as the EU15 figures, utilizing methodologies that allow for structural breaks. The results show poor fiscal performance in the European Union in general, suggesting that monetary unions do not necessarily encourage fiscal convergence for its members.

1. Introduction, Motivation, and Our Approach

In this paper, we study fiscal convergence in the enlarged European Union (EU). Our general measure of fiscal convergence is based on satisfying Maastricht fiscal criteria that require prudent fiscal behavior by the new members before their entry to the EMU. We examine the performance of the ten EU newcomers, as well as that of the Eurozone by using alternative measures of fiscal convergence by employing tests that allow for structural breaks. Our results suggest questionable fiscal convergence in the EU in general and large heterogeneity in convergence in particular.

Our study is motivated by the increasing attention fiscal performance in the EU has been receiving since the formulation of the convergence criteria under the Maastricht treaty in 1992.¹ Over the time, the two fiscal criteria limiting the deficit and debt ratios within a percentage of GDP have come under sharp scrutiny.² These conditions were set to allow qualifying countries to form the Economic and Monetary Union (EMU) in 1999. After this formation, empirical literature has turned to analyzing the new EU fiscal framework under the Stability and Growth Pact and its reform.³

Our study explicitly compares fiscal convergence trends during Accession, Membership and the Stability Growth Pact periods. It also considers ten new members that joined the EU in May 2004⁴, as well as groups of the EU core and periphery countries. As all of the newcomers must eventually join the Eurozone once they satisfy the Maastricht criteria, several observers have raised concerns about the poor fiscal performance of some new members.⁵ Many of the new EU members have therefore been put under the Excessive

² See, for example, Corsetti and Roubini (1995), and Holzman, Herve and Demel (1996).

³ Buti and Giudice (2002), Orban and Szapary (2004), Tanzi (2004), Eichengreen (2005), Eijffinger (2005), Feldstein (2005), and Schuknecht (2005).

⁴ Eight of them were Central and Eastern European countries (hereafter the CEE8), namely the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, the Slovak Republic, and Slovenia. The other new members were Cyprus and Malta. Slovenia joined the Eurozone in 2007. Slovak Republic was approved to join it in 2009.

⁵ Berger, Kopits and Szekely (2004) point out that deteriorating fiscal performance, especially in Central European countries, may constrain these members from satisfying the Maastricht criteria successfully because

Deficit Program (EDP) since their entry in 2004. In this respect, our empirical study offers an alternative way to evaluate the necessity for the EDP.⁶

Theoretical literature on fiscal convergence is scant. Based on a simple game theoretical framework where agents agree on the long-term goals, Onorante (2004) shows that fiscal constraints lead to implicit coordination characterized by lower deficits, low interest rates and controlled inflation. The model provides an argument for benefits of fiscal convergence for acceding country and the stability of the existing monetary union. In this respect, existing empirical literature on fiscal policy coordination in the EU countries provides support to theoretical benefits of fiscal convergence in large (e.g., Knot and de Haan, 1995; Sanz and Velázquez, 2003; Arestis, Khan, and Luintel, 2002; Faini, 2006; Afonso and Rault, 2007).

There is also ample evidence that fiscal convergence is systematically associated with enhanced business cycle synchronization as it eliminates idiosyncratic fiscal shocks along with evidence that reduced primary fiscal deficits (or higher surpluses) increase the coherence of business cycles across countries (Darvas, Rose, and Szapáry, 2005; Artis, Fidrmuc, and Scharler, 2008). It is argued that the increased business cycle coherence along with fiscal convergence makes countries within the region better candidates for a currency union (Darvas et al. 2005).⁷

Given limited studies on fiscal convergence, in particular, for the new-EU states, and its importance for EU policymakers, we contribute to the literature by providing a comprehensive empirical study on fiscal convergence of the new EU members to not only the Maastricht benchmark but against that of EU15. We relate the fiscal convergence to the

continuing large fiscal deficits can create inflationary pressures. Further arguments in the same spirit are voiced by De Grauwe and Schnabl (2004).

⁶ Since the underlying idea in fiscal rules of the EU is debt sustainability, our paper is related to recent studies on debt sustainability of developed and developing countries (e.g., Uctum, Thurston and Uctum, 2006; Uctum and Wickens, 2000), as well as fiscal sustainability in the EU15 in general (i.e., Afonso and Rault, 2007; Hughes Hallett and Lewis, 2007).

⁷ Since both the Maastricht convergence criteria and the Stability and Growth Act require prudent fiscal behavior before entry to the EMU, they indirectly move EU closer to an optimum currency area in the sense of Mundell (1961). Fidrmuc and Korhonen (2003 and 2006) show that at least some new members have already achieved a sufficient degree of business cycle synchronization.

progress in managing public finances and specific risks that policymakers in the new members must overcome in the process of joining the Eurozone. To measure fiscal convergence (to different benchmarks), we employ *beta*- and *sigma*-convergence tests, allowing for structural breaks. Towards this end, we use a test developed by Vogelsang (1998) which is particularly suitable for analyzing absolute convergence.⁸ In this approach, we are confronted with the existing empirical evidence on structural breaks in many economic indicators during the transition and pre-accession process in the Central and Eastern European (CEE) countries.⁹ Since such structural breaks in economic series may distort the findings, we employ the modified version of the Vogelsang test that allows for structural breaks (see Methodology section for details). His method not only allows for structural breaks but is also flexible enough to allow researchers to derive convergence estimates reliably, yielding more reliable inference about fiscal convergence than those found in earlier studies.

One of the ways to test for the fiscal convergence of the new members towards the EU is to compare their distance from convergence criteria as set in the Maastricht Treaty: (1) fiscal deficit up to 3% of GDP and (2) national debt up to 60% of GDP. In this respect we do not dispute or discuss the choice of the two ratio-values. Instead we complement the previous criteria with an alternative way of measuring the fiscal convergence in the EU newcomers with respect to the two synthetic benchmarks: (1) the EU core represented by Austria, Belgium, France, Germany and the Netherlands, and (2) the EU periphery represented by Greece, Portugal, and Spain. This alternative measure of fiscal convergence

⁸ Until recently, the cross-sectional tests used in analyzing absolute convergence were criticized for over-rejection of the null hypothesis of no convergence (Bernard and Durlauf 1996), shifting the emphasis to conditional and stochastic convergence. However, the need to meet the EU criteria for full EMU membership has regenerated interest in absolute convergence.

⁹ See e.g. Dibooglu and Kutan (2001), Kočenda (2005), and Égert et al. (2006). Further, it has to be recognized that the transition alone represented a massive structural shift by definition.

is in the spirit of the Stability and Growth Act since we test whether any of the new EU members have been performing like the old EU countries (EU15).¹⁰

In the next section, we introduce the methodology and in section 3 we describe our data. Empirical results are reported in Section 4. The last section concludes and provides some policy implications.

2. Methodology

The analysis of convergence has been an active as well as a challenging field of interest since the late 1980s.¹¹ Numerous methods have been used to analyze different measures of convergence, namely absolute or conditional beta-convergence, sigma-convergence, and stochastic convergence. While the former two types analyzed the issue of catching up, the latter and more recent focused on the synchronization of shocks and cross-sectional units moving together in time. The enlargement of the EU has refocused interest in the issue of the “catching up” of the new entrants to the core EU members. Cross-sectional tests mostly used to analyze β -convergence were criticized on the grounds of over-rejecting the null hypothesis of no convergence (Quah 1996, Bernard and Durlauf 1996). These criticisms pushed researchers to apply time series (or panel data) methodologies to introduce a second dimension to β -convergence.

A new test introduced by Vogelsang (1998, 1999) deals with the β -convergence issue by relying on time-series methodology.¹² Following this literature, we consider a simple model of convergence towards a benchmark as

$$y_t = \mu + \delta t + \gamma x_t + u_t \quad (1)$$

where y_t is the log difference of a variable from a benchmark, in our case for example, the budget deficit-to-GDP ratio of country i minus the Maastricht (or other) benchmark at time

¹⁰ For evidence on considerable monetary convergence within new EU members, see Kočenda (2001), Kutan and Yigit (2004, 2005). Brada et al. (2005) and Kutan and Yigit (2007) provide evidence on real convergence within new EU members and recent EU members, respectively.

¹¹ For recent discussions, see Taylor (1999) and de la Fuente (2002).

¹² See Tomljanovich and Vogelsang (2002) for its application on US data.

t ; μ is an intercept to capture the initial level of the deviation, t is a deterministic time trend, x_t includes control variables if any, and u_t is the residual term. In such a set-up, β -convergence requires that for countries where μ is initially significantly negative, so the country is lagging behind, the trend coefficient δ should have the *opposite* sign (positive) and be statistically significant. Carlino and Mills (1993) developed this test with a very restricted form of serial correlation for the residual term, namely AR(2). Vogelsang (1998) extended the analysis of this specification to u_t with an unknown form of serial correlation, allowing for specifications ranging from integration of order zero, $I(0)$, to order one, $I(1)$. Since the possibility of no convergence implies nonstationarity of the error terms, one can draw a false inference on the trend coefficient when the errors are assumed to be stationary AR(2).¹³ Vogelsang's (1998) methodology, in the spirit of Equation 1, considers the following Partial Sums with J correction (PSW) test statistic that helps to alleviate the above problems.¹⁴ It is defined as:

$$PSW_T = T^{-1} (R\hat{\beta} - r)' \left[R(X'X)^{-1} R' \right]^{-1} (R\hat{\beta} - r) / \left(100T^{-1} s_z^2 \exp(bJ_T(m)) \right) \quad (2)$$

where X and β consist of $[1 \ t]$ and $[\mu \ \delta]$ respectively, s_z^2 is the standard deviation of the partial cumulated sum of y_t and J_T is the Park and Choi (1988) unit root test statistic obtained from the following regression

$$y_t = X_t \beta + \sum_{i=2}^m c_i t^i + u_t \quad (3)$$

$$J_T(m) = (RSS_y - RSS_J) / RSS_J$$

In other words, J_T is the Wald statistic that tests the joint hypothesis of $c_2 = \dots = c_m = 0$. In Monte Carlo simulations, Vogelsang (1998) finds the values of b and m for which the

¹³ When u_t is $I(1)$, the estimate of β obtained from the above regression is not related to the true trend, and information on β must be obtained from the estimate of the intercept in the autoregressive representation of y_t .

¹⁴ See Vogelsang (1998) for further test statistics and a deeper elaboration of the tests.

above tests would be comparable and valid for every type of serial correlation form, including unit roots.

Despite the great flexibility of these tests in deriving the mean and trend coefficient estimates in time series with varying stationarity properties, one needs to be careful in using this methodology in the analysis of post-transition economies. The reason stems from the volatile nature of these economies and the presence of structural shifts that are documented in the empirical literature (e.g. Dibooglu and Kutan 2001; Kočenda, 2005; Égert et al., 2006).

We obtain robust results by using Vogelsang's (1999) methodology that allows for structural breaks in the modification of the statistics by including the possibility of shifts in the trend function. The test has been designed in two versions: one with predetermined breaks and the other with endogenous break selection. We favor the latter one. First, we estimate the break date using the optimal tests of Andrews and Ploberger (1994). Then, using the estimated break date, normalized critical values are obtained using the following altered version of Equation (1)

$$y_t = \mu_1 DU_{1t} + \mu_2 DU_{2t} + \delta_1 DT_{1t} + \delta_2 DT_{2t} + \gamma x_t + u_t \quad (4)$$

where $DU_{1t} = 1$ if $t \leq T_b$ (the break date) and zero otherwise, $DU_{2t} = 1$ if $t > T_b$ and zero otherwise, $DT_{1t} = t$ if $t \leq T_b$ and zero otherwise, and finally $DT_{2t} = t - T_b$ if $t > T_b$ and zero otherwise.

To derive inferences on fiscal convergence we test the significance and the opposite signs in the pair of coefficients, μ_1, δ_1 and μ_2, δ_2 . The null hypothesis is that trend coefficients are equal to zero, which in our framework translates to no trend in developments of budget deficit or debt. An alternative hypothesis of trend coefficients being statistically different from zero indicates existence of positive or negative trends in developments of both measures, depending on the sign. In particular, the finding of (statistically significant) mean and trend coefficients with opposite signs indicates how countries with different starting positions approach the benchmark. As an example consider

the dependent variable being the budget deficit (surplus) to GDP ratio in country i minus the 3% deficit benchmark. Then a positive intercept indicates a surplus or a deficit ratio below 3% since the negative 3% benchmark subtracted from a less negative deficit ratio yields positive value. Accordingly, a positive trend coefficient indicates improving comparative fiscal stance. The reverse follows for the opposite combination of signs. We supplement these results by tests of σ -convergence¹⁵ since confirmation of absolute convergence requires both β - and σ -convergence.

Granted that the Vogelsang (1999) methodology allows for only a single break, and it is desirable to use methodologies allowing for more breaks like Bai and Perron (BP henceforth, 1998), data availability and the performance of BP under $I(1)$ errors prevent us from pursuing these alternative methodologies. Uctum et al. (2006) analyze the mean reversion of the debt of developed and developing countries to examine sustainability by using a combination of the BP and Zivot and Andrews (1992) tests. These tests revolve around the same idea by testing for the mean reverting trends and temporary fluctuations around them in the existence of breaks, hence, broken trend stationarity. We prefer the Vogelsang methodology since it gives more accurate inference on the trend functions, and breaks in them, regardless of the (non)stationarity of the data series.¹⁶ This way, one does not have to test for the stationarity of the series around the trend values to evaluate convergence to benchmarks (or debt sustainability in the case of Uctum et al., 2006).

3. Data and Sample Period

We assess fiscal convergence of the CEE8, Cyprus, and Malta using the official Maastricht criteria of the deficit-to-GDP and debt-to-GDP ratios.¹⁷ We further examine fiscal convergence of these countries with respect to two naturally produced benchmarks. These

¹⁵ Sigma-convergence occurs when the cross-sectional standard deviation of a variable for a group of economies decrease in time.

¹⁶ The determination of the structural break date in Uctum et al (2006) and our paper is quite similar.

¹⁷ In terms of country coverage of the new EU member states, our paper is related to Hughes Hallett and Lewis (2007), but their focus is on fiscal sustainability, rather than fiscal convergence. They study debt dynamics for the eight new members from Central and Eastern Europe that are part of our sample as well.

are deficit and debt ratios achieved in the core of the EU, represented by the average values in Austria, Belgium, France, Germany and the Netherlands, and the EU periphery, represented by average values from Greece, Portugal and Spain. An analysis of the deficit and debt ratios is also consistent with testing the theoretical implications of the disciplining effects of monetary unions. We include GDP growth rate as a control variable in the deficit regressions in order to incorporate cyclical effects on deficit.

We use quarterly data from 1995:1 through 2005:4 for variables under research. The time span was chosen because: 1) official EU membership applications started in 1995, and 2) EuroStat began using the harmonized time series on macroeconomic variables at that time, and 3) consistent data are available for all countries through end of 2005. In addition, the post-1995 period excludes the major transition-related shocks observed in the early 1990s. The data are obtained primarily from the EuroStat database and checked for consistency against the International Financial Statistics of the IMF. In case of missing or incomplete observations, data are gathered from the individual central banks and finance ministries.¹⁸ We also annualize the quarterly debt and deficit data by summing the four quarters and then using this sum to obtain the deficit-to-GDP and debt-to-GDP ratios. We should reiterate at this point that the serial correlation generated by the methodology used for de-seasonalizing the data is of little concern here since the Vogelsang test is able to handle broad forms of serial correlation.

4. Empirical Findings

The Vogelsang test results are displayed in Tables 1 through 2. They display the results for *PSW* (Partial Sums with *J* correction) tests, given by the specification in Equation 2. The initial column in each table lists country variables. The next pair of columns for μ_1 and δ_1 corresponds to pre-break mean and growth rates, respectively. In a similar manner, there

¹⁸ In some cases, quadratic interpolation of annual data was necessary to fill some missing data points because the empirical methodology we use relies on uninterrupted data. Quadratic interpolation of annual data was used for debt in the case of Austria, Estonia, France, Germany, and the Netherlands, and for the Portuguese deficit and second half of the Greek deficit.

are two columns headed by μ_2 and δ_2 for post-break mean and growth rates. The last column contains the estimated break date using the maximum $T^{-1}W_T$ statistic of Andrews and Ploberger (1994). Following the theoretical grounds of the methodology employed, we apply a 10% trimming from each end of the sample since the break dates close to the endpoints are unreliable and should mostly be disregarded.¹⁹ We display the test statistics below the coefficient estimates and the asymptotic critical values for the endogenous break option of the *PSW* tests at the bottom rows of each table, respectively.

When interpreting results, the readers should note that positive trend coefficients represent *improvements* of fiscal position in comparison to the Union, suggesting that new EU members improve their fiscal position with respect to the old Union members. For instance, a positive trend coefficient shows new members' fiscal position is improving further, away from the 3% deficit benchmark. In short, a positive trend coefficient is always good. We supplement this brief explanation at the bottom of each table by indicating the dependent variable and providing a brief guideline to interpret the results easily.

The dependent variables in the analyses are the ratio of the budget deficit (surplus) to GDP and total debt to GDP in a new member country minus the benchmarks, 3% for deficit and 60% for total debt. Since all deficits (debt) are indicated by a negative number (e.g., minus 2% stands for two percent deficit), all mean values that are positive indicate surplus or deficit (debt) ratios below (less negative) 3% (60%), values that are zero indicate deficit (debt) of exactly 3% (60%), and values that are negative indicate deficit (debt) ratios greater than 3% (60%). As the GDP growth is used as a control variable accounting for cyclical deficit movements, we modify the test specification according to the choice of benchmark. While we use the country specific growth levels in the 3% benchmark regressions for instance, we prefer growth deviations for the core and periphery regressions.

¹⁹ Due to our small sample size, we run auxiliary Monte Carlo simulations to check the validity of the Vogelsang (2001) methodology. We run 5000 simulations with generated series with structural breaks (both in the mean and trend) to find that the methodology performs well in getting the true point estimates only with wider standard errors in comparison to the Vogelsang study. These simulations also show that the test performs well under 10% percent trimming even in small samples. Simulation results are available upon request.

Accordingly, negative trend coefficients depict deficit (debt) increases (or declining budget surpluses) with respect to the benchmark, suggesting fiscal divergence relative to the benchmark, and positive coefficients suggest just the opposite (fiscal convergence).

As a complementary measure of fiscal convergence, we also report the σ -convergence tests to be able to test whether the fiscal position of the new EU members are diverging or converging towards the core and periphery EU members. We illustrate the σ -convergence levels graphically. One should note that since the sigma (standard deviation in our case) is calculated cross-sectionally, the choice of benchmark does not alter the results.

4.1 Fiscal Convergence: Budget Deficit results

Table 1 examines whether the mean and trend coefficients of Equation (4) are *i*) statistically different from zero, implying that there is a positive or negative trend in budget deficits and, *ii*) have opposite signs, indicating that countries with higher (or more negative) deficit approach the benchmark or each other. Initially, one becomes aware of the fact that the pre-accession period (before 2000) is represented by significant levels of lack of fiscal convergence. The pattern that emerges from the table in general is that the earlier lack of fiscal convergence subsides as membership gets closer and that the countries with higher level of non-convergence tend to perform with more discipline than the ones with low deficits (better convergence).

The deficit-to-GDP ratio with respect to the benchmark of the core shows in essence a confirmation of the 3% benchmark (Table 1) results. All new members worsen their deficit position in comparison to the core countries, which can be noted from the significantly lower post-break means. Initially, better fiscal positions of these countries in comparison to the core imply that their attention was focused elsewhere. In other words, the new members have higher unjustified expansion in their deficits than the core countries. The Czech Republic, Baltic countries and Slovakia are the countries who try to improve on their poor pre-break performance by having positive trends in the second half of the sample period. The observed fiscal non-convergence conclusion is strengthened even more when we

compare the new members with the periphery. The drastic difference in fiscal position between the new members and the periphery at the beginning of the sample period had not only been closed in all countries, but it reverses direction in many countries. This indicates that of all the 3 groups the periphery has controlled its unjustified deficits the best. Latvia and Estonia are the only new-EU countries to have a higher trend in their budget performance in the second half of the sample period. In short, the difference between the new members and the core and periphery regressions point towards more fiscal convergence in the EU15 than the ten new members.

Inspecting Figure 1a for sigma convergence, one notices that the older EU members are quite in conjunction with one another while the new 10 members show a very slow decline in their cross-sectional standard deviation. Accounting for the average mean deficit of each group (Figure 1b) confirms this finding with the deficit condition of the new members exhibiting an inferior trend when compared to the older members. The periphery countries show constant decline in the mean and standard deviation of the deficit ratio while the core countries seem to lose focus after 2001. Mean ratio of the newcomers shows no improvement (or decline) with a flat trend during the period under research. The old members seem to be converging to a higher than desired equilibrium. From this perspective, convergence of the newcomers in terms of deficit-to-GDP ratio towards either the core or the periphery looks like a dubious enterprise, confirming the necessity of EDP.

4.2 Fiscal Convergence: Debt results

Convergence of the general government debt-to-GDP ratio towards the Maastricht benchmark of 60% as well as towards the core and periphery is displayed in Table 2 and Figure 2, in a similar fashion as with the budget deficit. The key dependent variable in Table 2 is the consolidated debt-to-GDP ratio in a new member country minus the 60% benchmark. A positive number indicates a debt ratio below 60% since the negative 60% benchmark subtracted from a less negative debt ratio yields positive values; thus, for example, a mean value of 40 means a 20% debt-to-GDP ratio. All countries, except

Hungary, start with a debt-to-GDP ratio lower than the Maastricht benchmark of 60% since the mean coefficients are all positive. The few positive trend coefficients observed in the pre-break period either reverse direction or lose significance in the post-break period, suggesting that the new member countries are increasing their debt-to-GDP ratio or showing lack of fiscal non-convergence. Countries like Malta and the Czech Republic stand out with the large deterioration of their indebtedness towards the benchmark.

A similar tendency and a clearer picture are observed when the 60% benchmark is replaced by the actual debt-to-GDP ratio in the core and the periphery. Again the big debt position difference at the beginning of the sample period narrows down the second half due to the fiscal indiscipline of the new members. Only Hungary stands out as the consistently prudent country among the new members. Estonia and Poland seem to show fiscal convergence either in post- and pre-2000, respectively, not displaying as consistent a picture as Hungary. A quick glance at Figure 2 shows that the slight decline in the core's debt situation, while the high debt of the periphery keeps the new members within comparatively acceptable debt positions. However, we can hardly call it a success story because their indebtedness increases in general and its dynamics are discomfoting.

Both results from Table 2 and the sigma convergence results in Figure 3a support earlier findings, as we observe that the new 10 members have outperformed the EU15 members, especially before 2001. Afterwards, their fiscal convergence loses some of its momentum as the variation of the debt positions of the new ten members evolve at par with the core after 2003. Fiscal convergence of the periphery starts to improve after 1996 but loses its original dynamics in 1998, further worsening in the recent period. The average debt ratios in Figure 3b confirm this finding since the periphery as well as the core show worse debt positions than the newcomers. On the other hand, its dynamics point at slowly diminishing debt position over the time. The results of the sigma convergence thus support better performance of the new members compared to the older ones but this finding is confronted with the worsening dynamics of their debt position.

5. Conclusions and Policy Implications

Our study examines the fiscal convergence of the new EU members with respect to EU15. Employing alternative measures of fiscal convergence and vastly flexible tests of convergence that allow for structural breaks, our study provides enhanced inference on fiscal convergence. An important finding that emerges from our study is that there exists a significant level of heterogeneity in fiscal convergence, raising concerns about the ability of monetary unions to provide fiscal convergence for its members. Given limited sample size, our results should be interpreted cautiously.

An important implication of our results is that the ongoing reform of the public finance systems in the whole EU27 is an agenda that is timely and should not to be underestimated. In the new EU members, this issue becomes even more important, because a neglect of public finance reforms and lack of fiscal convergence could lead to endangering completion of the Maastricht criteria and the consideration of entry into the Eurozone.

Our findings suggest the need to design further policies to improve fiscal performance. For example, EU policymakers may consider adopting fiscal policy rules, rather than a counter-cyclical fiscal policy. Some countries, such as Poland and the Netherlands, have already introduced fiscal rules into the laws and constitutions (Tanzi, 2005). Of course, the fact that the member states have different fiscal positions certainly creates implementation problems, at least initially. Tanzi suggests that “flexibility is required as to the time needed to conform to the rule, but the rule should not be relaxed to the point of making sinning more acceptable for everyone” (p. 63).

<i>Crit. Val.</i>					
5%	1.51	1.88	1.92	1.81	
10%	1.21	1.58	1.65	1.54	

Note: The first dependent variable is the budget deficit (surplus) to GDP ratio in country i minus the 3% deficit benchmark (a positive number indicates a surplus or a deficit ratio below 3% since the negative 3% benchmark subtracted from a less negative deficit ratio yields positive values). For the core (periphery), it is the deficit to GDP ratio in country i minus the core (periphery) deficit ratio (hence a negative number indicates a deficit ratio worse than that of the core (periphery) and a positive trend indicates lowering comparative deficit ratios). Hence, a positive trend coefficient indicates improving comparative fiscal stance. GDP growth (differences when necessary) has been used to control for cyclicity. The numbers in the parentheses for the above table and those that follow below indicate the test statistic associated with the coefficient estimate and are to be compared with the critical values at the bottom of the table. **(*) indicates 95%(90%) significance. Significance levels of breaks are determined using the critical values in Andrews and Ploberger (1994).

Table 2: Consolidated Debt/GDP Convergence to Maastricht Benchmark as well as the core and the periphery
